Math Facts Useful for Graduate Macroeconomics

The following collection of facts is useful in many macroeconomic models. No proof is offered in most cases because the derivations are standard elements of prerequisite mathematics or microeconomics classes; this handout is offered as an aide memoire and for reference purposes.

Throughout this document, typographical distinctions should be interpreted as meaningful; for example, the variables $r$ and $r'$ are different from each other, like $x$ and $y$.

Furthermore, a version of a variable without a subscript should be interpreted as the population mean of that variable. Thus, if $R_{t+1}$ is a stochastic variable, then $R$ denotes its mean value.

1 Utility Functions

1.1 [CRRALim]

Fact 1.

$$\lim_{\rho \to 1} \left( \frac{c^{1-\rho} - 1}{1 - \rho} \right) = \log c$$  \hspace{1cm} (1)

which follows from L'Hôpital's rule because for any $\rho \neq 1$ the derivative exists,

$$u'(c) = c^{-\rho},$$  \hspace{1cm} (2)

and $\lim_{\rho \to 1} c^{-\rho} = 1/c$ but $\int (1/c) = \log c$.

Thus, we can conclude that as $\rho \to 1$, the behavior of the consumer with $u(c) = c^{1-\rho}/(1 - \rho)$ becomes identical to the behavior of a consumer with $u(c) = \log c$.

1.2 [FinSum]

Fact 2.

$$\sum_{i=0}^{T} \gamma^i = \left( \frac{1 - \gamma^{T+1}}{1 - \gamma} \right)$$  \hspace{1cm} (3)

---

1\textsuperscript{Given recent decrees of the relevant authorities, the circumflex may need to be eliminated from future versions of these notes. Which is OK, because the gentleman in question paid someone smarter for the result anyway.}

2\textsuperscript{Recall that behavior is not affected by adding a constant to the utility function ...}
1.3 [InfSum]

Fact 3. If $0 < \gamma < 1$, then
\[
\sum_{i=0}^{\infty} \gamma^i = \left( \frac{1}{1 - \gamma} \right)
\] (4)

2 ‘Small’ Number Approximations

Sometimes economic models are written in continuous time and sometimes in discrete time. Generically, there is a close correspondence between the two approaches, which is captured (for example) by the future value of a series that is growing at rate $g$.

\[ e^{gt} \text{ corresponds to } (1 + g)^t \equiv G^t. \] (5)

The words ‘corresponds to’ are not meant to imply that these objects are mathematically identical, but rather that these are the corresponding ways in which constant growth is treated in continuous and in discrete time; while for small values of $g$ they will be numerically very close, continuous-time compounding does yield slightly different values after any given time interval than does discrete growth (for example, continuous growth at a 10 percent rate after 1 year yields $e^{0.1} \approx 1.10517$ while in discrete time we would write it as $G = 1.1$.)

Many of the following facts can be interpreted as manifestations of the limiting relationships between continuous and discrete time approaches to economic problems. (The continuous time formulations often yield simpler expressions, while the discrete formulations are useful for computational solutions; one of the purposes of the approximations is to show how the discrete-time solution becomes close to the corresponding continuous-time problem as the time interval shrinks).

2.1 [TaylorOne]

Fact 4. For $\epsilon$ near zero (‘small’), a first order Taylor expansion of $(1 + \epsilon)\zeta$ around 1 yields
\[
(1 + \epsilon)\zeta \approx 1 + \epsilon \zeta
\] (6)

2.2 [TaylorTwo]

Fact 5. For $\epsilon$ near zero (‘small’), a second order Taylor expansion of $(1 + \epsilon)\zeta$ around 1 yields
\[
(1 + \epsilon)\zeta \approx 1 + \zeta \epsilon + \epsilon^2 \zeta (\zeta - 1)/2
\] (7)
\[ = 1 + \left(1 + \left(\frac{\zeta - 1}{2}\right)\epsilon\right)\zeta\epsilon \quad (8) \]

2.3 [LogEps]

**Fact 6.** For \( \epsilon \) near zero (‘small’),

\[
\log(1 + \epsilon) \approx \epsilon \quad (9)
\]

2.4 [ExpEps]

**Fact 7.** For \( \epsilon \) near zero (‘small’),

\[
(1 + \epsilon) \approx e^\epsilon \quad (10)
\]

2.5 [OverPlus]

**Fact 8.** For \( \epsilon \) near zero (‘small’),

\[
1/(1 + \epsilon) \approx 1 - \epsilon \quad (11)
\]

2.6 [MultPlus]

**Fact 9.** For \( \epsilon \) and \( \zeta \) near zero (‘small’),

\[
(1 + \epsilon)(1 + \zeta) \approx 1 + \epsilon + \zeta \quad (12)
\]

2.7 [ExpPlus]

**Fact 10.** For real numbers \( \epsilon \) and \( \zeta \)

\[
\exp(\zeta)\exp(\epsilon) = \exp(\zeta + \epsilon) \quad (13)
\]

2.8 [SmallSmallZero]

**Fact 11.** If \( \epsilon \) is small and \( \zeta \) is small then \( \epsilon\zeta \) can be approximated by zero.

### 3 Statistics/Probability Facts

3.1 [SumNormsIsNorm]

**Fact 12.** If \( r_{t+1} \sim \mathcal{N}(r, \sigma_r^2) \) and \( r_{t+1} \sim \mathcal{N}(r, \sigma_r^2) \) and \( r_{t+1} \) and \( r_{t+1} \) are independent (written \( r_{t+1} \perp r_{t+1} \)) then

\[
r_{t+1} + r_{t+1} = \mathcal{N}(r + r, \sigma_r^2 + \sigma_r^2) \quad (14)
\]
3.2 [ELogNorm]

**Fact 13.** If from the viewpoint of period $t$ the stochastic variable $R_{t+1}$ is lognormally distributed with mean $r$ and variance $\sigma_r^2$, $R_{t+1} \sim N(r, \sigma_r^2)$, then

$$E_t[e^{R_{t+1}}] = e^{r + \sigma_r^2/2} \quad (15)$$

3.3 [ELogNormMeanOne]

**Fact 14.** If from the viewpoint of period $t$ the stochastic variable $R_{t+1}$ is lognormally distributed with mean $-\sigma^2/2$ and variance $\sigma^2_r$, $\log R_{t+1} \sim N(-\sigma^2/2, \sigma^2)$, then

$$E_t[e^{R_{t+1}}] = e^{-\sigma^2/2 + \sigma^2_r/2} = e^0 = 1 \quad (16)$$

3.4 [LogELogNorm]

**Fact 15.** If $R_{t+1}$ is lognormally distributed as in [ELogNormMeanOne], then

$$ \log E_t[R_{t+1}] = E_t[\log R_{t+1}] + \sigma^2_r/2$$

$$ = r + \sigma^2_r/2 \quad (17)$$

which follows from taking the log of both sides of (15).

3.5 [NormTimes]

**Fact 16.** If $r_{t+1} \sim N(r, \sigma_r^2)$, then

$$\gamma r_{t+1} \sim N(\gamma r, \gamma^2 \sigma_r^2) \quad (19)$$

3.6 [MeanOne]

**Fact 17.** If $\log R_{t+1} \sim N(-\sigma^2_r/2, \sigma^2_r)$, then

$$E_t[R_{t+1}] = 1 \quad (20)$$

for any value of $\sigma^2_r \geq 0$.

This follows from substituting $-\sigma^2_r/2$ for $r$ in [ELogNorm].

3.7 [LogMeanMPS]

**Fact 18.** If $\log R_{t+1} \sim N(r - \sigma^2_r/2, \sigma^2_r)$, then

$$\log E_t[R_{t+1}] = r \quad (21)$$

for any value of $\sigma^2_r \geq 0$.

This follows from substituting $r - \sigma^2_r/2$ for $r$ in [ELogNorm] and taking the log.
3.8 [ELogNormTimes]

**Fact 19.** If $\log \hat{R}_{t+1} = \gamma \log R_{t+1}$ where $\log R_{t+1} \sim N(\sigma_r^2)$, then

$$E_t[\hat{R}_{t+1}] = e^{\gamma r + \gamma^2 \sigma_r^2/2}$$

(22)

3.9 [LogELogNormTimes]

**Fact 20.** If $\log \hat{R}_{t+1} = \gamma \log R_{t+1}$ where $\log R_{t+1} \sim N(z,\sigma_r^2)$, then

$$\log E_t[\hat{R}_{t+1}] = \gamma r + \gamma^2 \sigma_r^2/2$$

(23)

which follows from taking the log of (22).

4 Other Facts

4.1 [EulersTheorem]

**Fact 21.** If $Y = F(K, L)$ is a constant returns to scale production function, then

$$Y = F_K K + F_L L,$$

(24)

and if this production function characterizes output in a perfectly competitive economy then $F_K$ is the interest factor and $F_L$ is the wage rate.
